

AO Universe Integration Architecture — Final Presentation Script

Slide 1 — AO Universe: Connected by Intention

Speaker script

“Today’s deck shows the completed AO Universe operating model. Homeworld is the navigation and identity surface. Sanctuary is the authenticated mission and reward-ledger authority. Originals is the living directory and story surface. Games, Arcade, Beat Lab, House 3, Archive, and future worlds remain distinct destinations with their own art, code, and deployment paths.

The result is not one flattened application. It is a connected constellation: separate products that share player context, deliberate handoffs, mission events, and a path back to the originating world.”

Key point: The universe is connected without erasing the worlds that make it alive.

Slide 2 — Deployment Topology: Separate Products, Clear Ownership

Speaker script

“Each product has a clear hosting and ownership boundary.

`anomartsy.xyz` now points to the Homeworld GitHub Pages deployment. Homeworld owns the map, the four-house experience, the shared bridge, games, Beat Lab, Arcade, and House 3 routes.

Sanctuary remains its own React application and is the authority for authenticated missions and ledger writes. Originals remains its own React application and serves the AO Alive directory, world registry, and discovery experience.

This separation lets each repository evolve independently while the user experience remains coherent.”

Key point: Domain routing, repository ownership, and application responsibility are explicit.

Slide 3 — The Destination Registry

Speaker script

“The destination registry is the source of truth for the AO map. Every destination has a stable identifier, display name, category, URL, integration level, and status.

The registry distinguishes same-domain routes such as Games, Arcade, Beat Lab, and House 3 from separate React applications such as Sanctuary and Originals. It also identifies kid-safe creative pathways and future source repositories without hardcoding disconnected navigation components.

When a new game or React document is discovered, it becomes a data entry first. That keeps the map extensible and keeps navigation behavior consistent.”

Key point: New worlds become registry entries, not one-off rewrites.

Slide 4 — The Shared AO Bridge

Speaker script

“The AO bridge carries the player context across every connected surface.

The core parameters are `house`, `mount`, `return`, and `source`. Mission-aware flows add `mission` and `event`. House identifies the player’s AO identity group. Mount identifies the selected companion or travel state. Return gives each destination a safe way back. Source preserves attribution. Mission identifies the shared objective, and event acts as the idempotency key.

Static surfaces load `assets/ao-bridge.js`. React applications use the `AOBridgeProvider` and the same context contract. URL parameters provide immediate continuity, while local storage preserves the lightweight client-side state needed between handoffs.”

Key point: One contract supports static games, kid-safe experiences, and React applications.

Slide 5 — End-to-End Player Journey

Speaker script

“The verified journey begins on Homeworld with House 3, the Mood Buddies identity, and the Aurora mount.

Homeworld generates a Sanctuary mission URL carrying the house, mount, return destination, source, mission, and event. Sanctuary receives the context and renders Connected Missions. From there, the player can continue the mission and eventually return to the AO surface.

The same context can travel into Originals, where the AO Alive experience preserves the URL parameters and exposes Sanctuary, Games, Library World, and Master Map destinations.

The browser-level test confirmed the complete parameter chain without losing identity or mission context.”

Key point: The player’s identity context survives the journey across products.

Slide 6 — Sanctuary: Mission and Reward-Ledger Authority

Speaker script

“Sanctuary owns the authenticated reward ledger. The public mission catalog can be listed without authentication. Mission status and completion require the protected procedure boundary.

The completion contract accepts a mission ID, event ID, source, house, and mount. The event ID is the idempotency key, so a repeated handoff cannot award the same mission twice. The ledger records the completion and balance snapshot atomically inside Sanctuary’s backend.

The integration test deliberately validated the public journey and protected contract without mutating a real player balance. A production completion test should use a dedicated test account and isolated ledger data.”

Key point: Context can be public; reward authority remains authenticated and centralized.

Slide 7 — Originals and the Discovery Layer

Speaker script

“Originals is the discovery and meaning layer of AO Alive. Its live page receives the bridge parameters, preserves the originating Sanctuary return path, and exposes the next destinations: Sanctuary, Games, Library World, Master Map, Anoms Corner, and future worlds.

The Originals mission helper creates a canonical Sanctuary handoff with `source=originals`, the active house and mount, the mission ID, and a unique event ID.

This means Originals can start a mission journey without owning the ledger. Sanctuary remains the place where authenticated completion is evaluated and rewards are recorded.”

Key point: Originals can initiate meaningful journeys while Sanctuary remains the reward authority.

Slide 8 — Kid-Safe Creative Loops

Speaker script

“Beat Lab and House 3 show how the shared architecture can support different emotional and developmental pacing.

Beat Lab is a kid-safe creative surface with large controls, mathematical sound generation, and no dependency on external samples. House 3 is a gentle Mood Buddies experience built around emotional recognition and simple choices.

Both can receive the same house, mount, return, and source context without changing their art direction or turning a child-facing page into a ledger interface.”

Key point: Shared infrastructure does not require shared tone or shared visual language.

Slide 9 — Cross-App Analytics Contract

Speaker script

“The analytics configuration turns the bridge into an observable journey system without collecting unnecessary personal information.

The tracked events include context received, destination viewed, handoff started, handoff landed, mission viewed, mission started, mission completed, ledger write result, and return clicked.

The dashboard measures unique journeys, handoff completion, mission conversion, ledger-write success, duplicate-event rate, and return-to-origin behavior. The primary dimensions are source, destination, house, mount, mission ID, ledger result, and device class.

The event model is privacy-safe by default: no raw payment information, no freeform messages, no child profile data, and no unredacted identity parameters.”

Key point: We can understand the universe’s flow without turning the bridge into a surveillance system.

Slide 10 — Verification and Operational Boundaries

Speaker script

“The end-to-end integration test verified the live Homeworld custom domain, the AO bridge runtime context, Games, Arcade, Beat Lab, House 3, Sanctuary Missions, and Originals.

It confirmed that `house=3`, `mount=aurora`, `mission=make-something-kind`, `event`, `source`, and `return` survive the cross-app journey. It also verified that Sanctuary’s direct `/missions` route renders through the GitHub Pages fallback and repository-base-aware router.

The test intentionally did not award production currency. Reward mutation belongs in an authenticated test-account run against isolated ledger data. That separation keeps navigation validation safe and makes ledger verification reproducible.”

Key point: Read-only journey tests are broad; reward mutations are isolated and intentional.

Slide 11 — Current Architecture and Next Safe Moves

Speaker script

“The current architecture is ready for disciplined expansion.

The next safe moves are to connect the analytics event sink, add a dedicated ledger test account, instrument mission completion and duplicate-event outcomes, and add new games through the destination registry.

After that, authenticated identity clusters can replace anonymous session continuity where appropriate. The bridge contract does not need to change. New capabilities can be layered onto the same stable handoff model.”

Key point: The foundation is stable enough to grow without forcing a rewrite.

Slide 12 — Closing: AO Alive

Speaker script

“AO Alive becomes social by being connected with intention.

Homeworld gives players a place to orient. Originals gives the universe meaning and discovery. Sanctuary gives missions and rewards a trusted home. Games, Beat Lab, Arcade, House 3, Archive, and future worlds give the player reasons to return.

The shared bridge carries identity context. The registry keeps the map extensible. The ledger keeps rewards authoritative. Analytics lets us understand the journey responsibly.

The worlds remain distinct. The experience becomes one universe.”

Closing line

“The AO universe becomes social by being connected with intention—not by erasing the worlds that make it alive.”
